FIG. 2

The diagram illustrates a time-to-digital converter (TDC) and the associated components and operations. The TDC input (TDC_in) and reference input (REF_in) are connected to the TDC block, which processes the time difference (\( t \)) between the two inputs. The error \( e[k] \) is calculated as \( 1 - (tr/Tv) \), where \( tr \) is the input rise time and \( Tv \) is the voltage level. The diagram also shows the code edge detector and the output \( et[k] \).

The diagram includes a block diagram with labeled components and connections, indicating the flow of signals and the processing steps within the TDC circuit.

FREQUENCY SYNTHESIZER AND ASSOCIATED METHOD

This application claims the benefit of U.S. provisional application Ser. No. 61/548,096, filed Oct. 17, 2011, the subject matter of which is incorporated herein by reference.

FIELD OF THE INVENTION

The present invention relates to a frequency synthesizer, and more particularly, to a frequency synthesizer including peripheral mechanism supporting time-to-digital conversion with improvement of reduced hardware complexity, lower power consumption, suppressed supply interference, reduced layout area and enhanced linearity, etc.

BACKGROUND OF THE INVENTION

Various communication systems, such as wireless communication systems of radio frequency (RF), are broadly adopted and play an important role in modern information society. A core technique for modern communication systems is frequency (and/or clock) synthesis, which generates a variable clock of a desired frequency based on a frequency reference clock, such that stability, accuracy, and spectral purity of the variable clock correlate with performance of the frequency reference clock. In a transmitter, the variable clock provided by a local frequency synthesizer can be utilized as a local oscillation carrier for an up-conversion frequency translation from baseband or intermediate-frequency (IF) signals to RF signals. On the other hand, in a receiver, the variable clock provided by a local frequency synthesizer can be adopted as a local oscillation carrier for a down-conversion from RF signals to IF/baseband signals.

SUMMARY OF THE INVENTION

A frequency synthesizer accepts a frequency reference clock and a frequency command word (FCW) for input, and outputs a variable clock in response, such that a frequency of the variable clock is an FCW multiple of the frequency reference clock. A high-speed variable clock of frequency in an order of GHz can therefore be generated based on a stable low-speed frequency reference clock of frequency in an order of tens of MHz, for example.

An embodiment of the invention provides a frequency synthesizer including a frequency reference input for receiving a frequency reference clock, a tuned oscillator for providing an RF clock, a phase shifter coupled to said frequency reference input and arranged to change phase of said frequency reference clock, and a time-to-digital converter (TDC) coupled to said phase shifter and said tuned oscillator for producing a digital TDC output, wherein a range of said TDC covers less than a full range of said RF clock period.

In an embodiment, said phase shifter is a digital-to-time (DTC) for delaying said frequency reference clock in response to a DTC digital control. In an embodiment, said DTC digital control is set in response to an accumulated value of FCW, and said phase shifter is therefore arranged to change phase of said frequency reference clock in response to said accumulated value of said FCW, e.g., a fractional part of said accumulated value of said FCW.

In an embodiment, said frequency synthesizer further includes a shift controller, a variable phase accumulator and a reference phase accumulator. Said variable phase accumulator is coupled to said tuned oscillator for accumulating a count of periods of said RF clock and providing a variable phase signal in response. Said reference phase accumulator is arranged to provide said accumulated value of said FCW by accumulating said FCW in response to each period of said frequency reference clock. Said shift controller is coupled to said phase shifter for providing a shift control signal (e.g., said DTC digital control) and an auxiliary fractional error correction signal in response to said accumulated value of said FCW. Said phase shifter is arranged to change phase of said frequency reference clock in response to said shift control signal, and said tuned oscillator is arranged to tune periods of said RF clock according to said digital TDC output, said auxiliary fractional error correction signal, said variable phase signal and said accumulated value of said FCW.

In an embodiment, said phase shifter is arranged to change phase of said frequency reference clock and to provide a shifted reference clock accordingly, such that a time difference between a transition of said shifted reference clock and a previous transition of said RF clock is less than said full range of said RF clock period. In an embodiment, said TDC is arranged to respond when a transition of said RF clock and a transition of said shifted reference clock occur in a proximity of said range, and not to respond when transitions of said RF clock and transitions of said shifted reference clock do not occur in a proximity of said range.

An embodiment of the invention provides a frequency synthesizer including an oscillator, a phase shifter, a DTC, a shift controller, a reference phase accumulator and a variable phase accumulator. Said oscillator is arranged to provide a variable clock. Said phase shifter is arranged to provide a shifted reference clock whose phase is arranged to be different from phase of a frequency reference clock by a phase offset, wherein said phase offset is such arranged that a time difference between a transition of said shifted reference clock and a prior transition of said variable clock is less than a period of said variable clock. Said TDC is coupled to said phase shifter and arranged to provide a first fractional error correction signal by quantizing said time difference.

Said reference phase accumulator is arranged to provide a reference phase signal by accumulating FCW in response to each period of said frequency reference clock; said variable phase accumulator is coupled to said oscillator for providing a variable phase signal by accumulating a count of periods of said variable clock. Said shift controller is coupled to said phase shifter, and arranged to provide a shift control signal and a second fractional error correction signal in response to said reference phase signal, such that said phase shifter is arranged to set said phase offset in response to said shift control signal, and said oscillator is arranged to tune periods of said variable clock according to said first fractional error correction signal, said second fractional error correction signal, said reference phase signal and said variable phase signal.

An embodiment of the invention provides a frequency synthesizer including an oscillator, a TDC, a shift controller as well as a phase shifter, a reference phase accumulator and a variable phase accumulator. Said oscillator is arranged to tune periods of a variable clock according to a first fractional error correction signal provided by said TDC, a second fractional error correction signal provided by said shift controller, a variable phase signal provided by said variable phase accumulator and a reference phase signal provided by said reference phase accumulator.

An embodiment of the invention provides a method of synthesizing a frequency by providing a variable clock, including: generating said variable clock in response to an oscillator tuning signal; phase shifting a frequency reference clock by a phase offset to obtain a shifted reference clock; and digitizing a timing difference of said variable clock and said
shifted reference clock such that a range of said digitizing covers less than a full range of said variable clock period.

In an embodiment, the method further includes: adjusting said phase offset, such that a time difference between a transition of said shifted frequency reference clock and a prior transition of said variable clock is less than or equal to a time difference between a transition of said frequency reference clock and a prior transition of said variable clock.

In an embodiment, the method further includes: obtaining an accumulated value of a frequency command word (FCW) by accumulating said FCW according to periods of said frequency reference clock, and adjusting said phase offset in response to a fractional part of said accumulated value of said FCW, obtaining a first fractional error correction signal in response to said digitizing, obtaining a second fractional error correction signal in response to said phase offset, and adjusting said oscillator tuning signal further in response to said first and second fractional error correction signals.

Numerous objects, features and advantages of the present invention will be readily apparent upon a reading of the following detailed description of embodiments of the present invention when taken in conjunction with the accompanying drawings. However, the drawings employed herein are for the purpose of descriptions and should not be regarded as limiting.

BRIEF DESCRIPTION OF THE DRAWINGS

The above objects and advantages of the present invention will become more readily apparent to those ordinarily skilled in the art after reviewing the following detailed description and accompanying drawings, in which:

FIG. 1 illustrates an embodiment of digitally tracking phases of a variable clock and a frequency reference clock; FIG. 2 illustrates an embodiment of a TDC; FIG. 3 and FIG. 4 respectively illustrate a frequency synthesizer and its operation according to an embodiment of the invention; FIG. 5 and FIG. 6 respectively illustrate a frequency synthesizer and its operation principle according to an embodiment of the invention; FIG. 7 and FIG. 8 respectively illustrate a frequency synthesizer and its operation according to an embodiment of the invention; FIG. 9 illustrates a frequency synthesizer according to an embodiment of the invention; FIG. 10 illustrates an embodiment of the power management circuit in FIG. 9 according to the invention; FIG. 11 illustrates an embodiment of the power management circuit in FIG. 9 according to the invention; FIG. 12 illustrates operation examples of the power management circuit in FIG. 11 according to an embodiment of the invention; and FIG. 13 illustrates an implementation example of the level sense circuit in FIG. 11 according to an embodiment of the invention.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

Please refer to FIG. 1 illustrating a conceptual embodiment for digitally tracking phases of a clock CKV and a clock FRE, such that frequency of the clock CKV is an FCW multiple of frequency of the clock FRE. That is, by assigning a corresponding FCW, a clock CKV of a desired frequency is produced based on a clock FRE. The clock FRE is a frequency reference clock of a period Tr. The clock CKV, generated by an oscillator 10, e.g., a digitally controlled oscillator (DCO), is a variable clock of a period Tv. For frequency synthesis, the oscillator 10 is tuned so that the clock CKV locks to the clock CKR, so frequency of the clock CKV approaches FCW multiple the clock FRE in the limit, i.e., the average period Tv equals Tr/FRE. The FCW is in general a real number with an integer part and a fractional part; in the example of FIG. 1, the FCW is 9/4 with an integer part equal to 2 and a fractional part equal to ¼.

To digitally represent phase of the clock CKV, a signal (e.g., a digital word) PHV[i] is provided. The signal PHV[i], as a variable phase signal, accumulates a unit count at every significant transition (e.g., rising edge) of the clock CKV, i.e., PHV[i+1]=PHV[i]+1 with index i indicating a time stamp of the i-th significant transition of the clock CKV. That is, as time progresses, the variable phase signal PHV[i] accumulates a count of periods of the clock CKV to reflect phase of the clock CKV in terms of the period Tv. The signal PHV[i] is an integer since it accumulates integers.

While digitally representing phase of the clock FRE, phase information of the clock FRE is synchronized with significant transitions of the clock CKV, so phase information of the clock FRE can be compared with the signal PHV[i], which updates at significant transitions of the clock CKV. Therefore, the clock FRE is re-timed to a clock CKR by a re-timer 12 (e.g., a flip-flop). The re-timer 12 is arranged to provide the re-timed reference clock CKR by re-timing the clock FRE' at significant transitions of the clock CKV, such that each transition of the clock CKR aligns with a significant transition of the clock CKV. In response to triggering of the clock CKR, a signal PHR[k] is provided to digitally reflect phase of the clock FRE. The signal PHR[k], as a reference phase signal, accumulates the FCW at every significant transition of the clock CKR, i.e., PHR[k+1]=PHR[k]+FCW, with index k indicating a time stamp of the k-th significant transition of the clock CKR.

As the period Tr of the clock FRE is expected to be an FCW multiple of the period Tv of the clock CKV, accumulating FCW on each period of the clock CKV is used to reflect phase of the clock FRE in terms of the period Tv. Since the FCW generally has a fractional part, the signal PHR[k] also has a fractional part in general.

Because the clock CKR is re-timed by the clock CKV, each significant transition of the clock CKV aligns with a significant transition of the clock CKR, then the signal PHR[k], i.e., the signal PHV[i] at k-th significant transition of the clock CKR, can be compared with the signal PHR[k]. In the example of FIG. 1, the signal PHV[0] aligns with the signal PHR[0], and the signal PHV[0+3]=PHV[3]+FCW synchronizes with the signal PHR[3+1], etc. As shown in FIG. 1, re-timing the clock FRE' to the clock CKR by triggering of the clock CKV induces an error e[k], representing a time difference (phase error) between a significant transition of the clock FRE' and a subsequent significant transition (i.e., the closest significant transition after the significant transition of the clock FRE) of the clock CKV.

In the example of FIG. 1, when the clock CKV locks the clock FRE' with the desired relation Tv=Tr/FRE, every four cycles of the period Tr will align with every nine cycles of the periods Tv, since FCW=9/4. That is, accumulating the FCW four times equals accumulating the unit count nine times, for FCW*4=(9/4)*4=9. Assuming the significant transitions of the clocks FRE and CKV align at the time stamp k0 such that the values of the signals PHR[k0] and PHV[0] are equal, then, after four cycles of the clock CKR, the significant transitions of the clocks FRE and CKV align again, and the value of the signal PHR[k0+4] also meets the value of the
signal PHV[k+9] (i.e., PHV[k+4]), because PHR[k+4] = PHR[k+1]*FCW^4, and PHV[k+9] = PHV[k+4]*1.9. On the other hand, owing to the fractional part of the FCW, the time stamp k progresses, the difference (PHV[k]-PHR[k]) between the signals signals PHV[k] and PHR[k]. For example, at the time stamp k+1, the significant transition of the clock FREF is ahead of the subsequent significant transition of the clock CKV by (1/4)*TV when the clock CKV locks the clock FREF, and the arithmetic difference between signals PHV[k+1] and PHR[k+1] indicates the time difference by (PHV[k+1]-PHR[k+1])=(3.9-9)/4. Similarly, at the time stamp k+2, the "misalignment" of (1/4)*TV between the significant transitions of the clock FREF and CKV is reflected by (PHV[k+2]-PHR[k+2])=(5-18/4)=-3/4).

As the time stamp k progresses, the difference (PHV[k]-PHR[k]) between the signals signals PHV[k] and PHR[k] varies regularly and periodically, and reflects a deterministic time difference (phase error) between the significant transitions of the clocks FREF and CKV in terms of the period Tt. Hence, the difference (PHV[k]-PHR[k]) becomes a deterministic part of the error e[k], reflecting a regular phase error due to the fractional part of the FCW. That is, when the clock CKV locks the clock FREF, the error e[k] equals (PHV[k]-PHR[k]), or PHR[k]-e[k]+PHV[k]-0.

The regular misalignment between the significant transition of the clock FREF and the subsequent significant transition of the clock CKV is in a range of one period Tt; equivalently, the difference (PHV[k]-PHR[k]), which leads to the deterministic part of the error e[k], is a fractional number in general (equal to zero). Since the signal PHV[k] is an integer, the deterministic part of the error e[k] is related to the fractional part of the PHR[k]. For practical application, the error e[k] also includes a fluctuating part of random nature, reflecting stochastic phase error due to noise of the oscillator etc.

To be more general, let the FCW be expressed by Nv/Nr with Nv and Nr being integers and Nv not an integer multiple of Nr, then the deterministic part of the error e[k] periodically repeats every Nr cycles of the clock CKR; that is, the deterministic parts of the errors e[k] and e[k+Nr] are equal, and can be predicted according to the fractional part of the accumulated value of the FCW (i.e., the signal PHR[k] and the signal PHV[k]. Assuming the signals PHV[k] and PHR[k] are equal at the time stamp k0, tuning the oscillator 10 to match integer parts of the signal PHR[k] and the integer-valued signal PHV[k] every Nr cycles of the clock CKR (e.g., at time stacks k0 and [k0+Nr], etc) suggests a frequency lock. However, as Nr cycles of the clock CKR covers many cycles of the clock CKV, the period TV of the clock CKV drifts or wanders if the error e[k] is not fully monitored during these Nr cycles of the clock CKR. For a finer phase lock, a time-to-digital converter (TDC) is therefore adopted to digitally detect the error e[k] every cycle of the clock CKR, so the oscillator 10 can be tuned according to a digital TDC output of the TDC to ensure (PHR[k]+e[k]-PHV[k]) approaches zero at each time stamp k.

Please refer to FIG. 2 illustrating an embodiment of a TDC 20. The TDC 20 is coupled to two inputs 22a and 22b for respectively receiving two signals TDC_in and REF_in, and outputs a signal e[k] as a digital TDC output. While the TDC 20 is adopted to detect the error e[k] shown in FIG. 1, the clocks FREF and CKV are respectively received as the signals REF_in and TDC_in. The TDC 20 is arranged to preferably quantize a time difference dt between a significant transition 16c of the signal REF_in and a subsequent transition 16c of the signal TDC_in, such that the sum of the number L of the delay units 18 (e.g., inverters), a plurality of flip-flops 24 triggered by the signal REF_in, and a code edge detector 26. Each delay unit 18 imposes a unit delay time t_inv to the signal TDC_in, and outputs the delayed signal to a corresponding flip-flop 24 and a next delay unit 18. When the significant transition of the signal REF_in triggers the flip-flops 24 to obtain a code of bits Q(1), Q(2), ..., Q(L), occurrence of the significant transition 16c is reflected by a code edge in the code of the bits Q(L) to Q(L), and the rise time tr is quantized in terms of the unit delay time t_inv by the code edge detector 26 and outputted as the signal e[k]. That is, a time quantization resolution of the TDC 20 is determined by the unit delay time t_inv of each delay unit 18. The total number L of the delay unit 18 determines a measuring range (a TDC range) of the TDC 20. The TDC range of the TDC is approximately L*t_inv. A time interval shorter than the TDC range can be measured, and a time interval longer than the TDC range is not detected by the TDC 20. While the TDC 20 is used to detect the error e[k] shown in FIG. 1, the TDC range should cover a full range of the period TV.

To detect the error e[k] in finer resolution for better quality of the clock CKV, the unit delay time t_inv is set much shorter than the period TV. Consequently, the TDC 20 needs a much larger number L of the delay unit 18 to cover a TDC range of the period TV. For example, to cover a period of 2.4 GHz with 7 ps resolution, about sixty delay units 18 are applied to implement the TDC 20. As more delay units 18 are adopted, more power is consumed, and more supply interference (equal to drop of supply voltages) is induced. To settle high supply interference, decoupling capacitors of large area must be utilized, and area to implement an effective TDC is therefore increased. Moreover, high supply interference degrades linearity of time-to-digital conversion, since amount of the unit delay time t_inv drifts when supply volt-
ages fluctuate. Therefore, supporting peripherals to reduce required delay units and to enhance linearity of TDC are demanded.

Please refer to FIG. 3 illustrating a frequency synthesizer 30 according to an embodiment of the invention. The frequency synthesizer 30 has an FCW input 32a for receiving FCW, a frequency reference input 32b for receiving a frequency reference clock FREF, a reference phase accumulator 34, a variable phase accumulator 36, a loop filter 38, an oscillator 10, a phase shifter 46, a shift controller 42, a TDC 40, an adder 50 and a re-timer 12. The oscillator 10 is arranged to provide a variable clock CKV, e.g., an RF clock, in response to an oscillator tuning word (OTW), such that the frequency of the variable clock CKV is FCW multiple of the frequency reference clock FREF when the variable clock CKV locks to the frequency reference clock FREF.

The re-timer 12 is coupled to the oscillator 10 and the frequency reference clock FREF, and arranged to provide a re-timed reference clock CKR by re-timing the frequency reference clock FREF at significant transitions (e.g., rising edges) of the variable clock CKV. The re-timing phase accumulator 34 is coupled to the frequency reference clock FREF through the frequency reference input 32b, and arranged to provide a reference phase signal PHR[k] by accumulating the FCW in response to each period of the frequency reference clock FREF, e.g., at significant transitions of the re-timed reference clock CKR.

In FIG. 3, the phase reference signal PHR[k] is decomposed to a fractional part PHRF1[k] and an integer part PHRF2[k]. The variable phase accumulator 36 is coupled to the oscillator 10, and arranged to provide a variable phase signal PHV[k] by accumulating a count of periods of the variable clock CKV.

The phase shifter 46 is coupled to the oscillator 10 and the shift controller 42, and arranged to provide a shifted variable clock CKV' by changing phase of the variable clock CKV in response to a shift control signal SEL. Alternatively, the phase shifter 46 could perform phase changing by selecting one of a multiple of CKV phases. The generation of the multiple phases could be done internally to the phase shifter 46. The TDC 40 functions similarly to the TDC 20 shown in FIG. 2; the TDC 40 is coupled to the phase shifter 46 and the frequency reference input 32b, arranged to receive the frequency reference clock FREF and the shifted variable clock CKV' as the signals REF_in and TDC_in, and arranged to provide a fractional error correction signal PHF1[k] in response to a time difference between the frequency reference clock FREF and the shifted variable clock CKV'. That is, the TDC 40 is arranged to detect (quantize) the time difference between a significant transition of the frequency reference clock FREF and a subsequent significant transition of the shifted variable clock CKV', and provide a signal et[k] to reflect the detected time difference; then the fractional error correction signal PHF1[k], indicating the time difference in terms of the period Tv of the variable clock CKV, is provided by normalizing the signal et[k] to an averaged period Tv_avg, which is a long-term average of the periods of the variable clock CKV, since the period Tv is in general a time-varying value.

To cooperate with the phase shifter 46, the shift controller 42 is coupled to the phase shifter 46 and arranged to provide the shift control signal SEL and another fractional error correction signal PHF2[k]. The adder 50 is coupled to the variable phase accumulator 36, the reference phase accumulator 34, the shift controller 42 and the TDC 40, and arranged to provide a signal PHE[k] in response to an arithmetic combination (PHR[k]+PHF1[k]+PHF2[k]+PHV[k]) of the reference phase signal PHR[k], the variable phase signal PHV[k] and the fractional error correction signals PHF1[k] and PHF2[k]. The loop filter 38 is coupled between the oscillator 10 and the adder 50, and arranged to provide the OTW in response to the signal PHE[k]. Thus, through the OTW, the oscillator 10 is arranged to tune periods of said variable clock CKV according to the reference phase signal PHR[k], the variable phase signal PHV[k] and the fractional error correction signals PHF1[k] and PHF2[k].

Please refer to FIG. 4 illustrating TDC operation of the frequency synthesizer 30 according to an embodiment of the invention. The phase shifter 46 (FIG. 3) is arranged to induce a phase offset PHoffset between the variable clock CKV and the shifted variable clock CKV'. With the phase offset PHoffset, the error (1-e[k]) between the frequency reference clock FREF and the previous variable clock CKV is decreased to a shorter error (1-e'[k]), i.e., decreased the timing separation between the frequency reference clock FREF and the shifted variable clock CKV', with -e[k]=e'[k]+PHoffset. In other words, the phase offset PHoffset is such arranged that a time difference between a significant transition of the frequency reference clock FREF and a previous significant transition of the shifted variable clock CKV' is significantly less than a period Tv of the variable clock CKV; i.e., the error -e[k] never grows larger than a portion of the period Tv. As the shifted variable clock CKV' and the frequency reference clock FREF are respectively received as the signals TDC_in and REF_in, the TDC 40 only needs to quantize the error -e[k] significantly shorter than the period Tv. In other words, the TDC range of the TDC 40 just needs to cover a portion of one period Tv, instead of full range of the period Tv. The TDC 40 is arranged to respond only when a significant transition of the shifted variable clock CKV' and a significant transition of the frequency reference clock FREF occur in a proximity of the TDC range; the TDC 40 does not have to respond when significant transitions of the shifted variable clock CKV' and significant transitions of the frequency reference clock FREF do not occur in a proximity of the TDC range. Since the required TDC range is decreased, the TDC 40 benefit from lower quantity of required delay units; hardware complexity, power consumption, layout area, supply interference and linearity degradation of TDC 40 are then reduced without compromising TDC resolution.

As discussed in FIG. 1, the error e[k] includes a time-varying but predictable deterministic part corresponding to (PHR[k]+PHV[k]). Based on the regularly varying deterministic part of the error -e[k], the shift controller 42 dynamically sets the phase offset PHoffset of the shift control signal SEL, such that the phase offset PHoffset is subtracted from the deterministic part of the error -e[k] to become the error -e'[k]. For example, when the deterministic part of the error -e[k] is predicted to be in a range of 1/4 (equivalent to a phase of 90 degrees) to 1/2 (180 degrees), the phase offset PHoffset can be set to 90 degrees (equivalent to 1/4), hence the error -e'[k] is maintained in a range of 0 to 1/4. Similarly, as time progresses, when the deterministic part of the error -e[k] enters a range of 1/2 to 3/4, the phase offset PHoffset tracks to be set to 180 degrees (1/2 in terms of the period Tv), so the error -e'[k] is kept in a range of 0 1/4. To compensate the subtracted phase offset PHoffset, the shift controller 42 injects the fractional error correction signal PHF2[k] to the adder 50 to reflect the phase offset PHoffset, with the fractional error correction signal PHF2[k] indicating the quantized error -e[k], the error -e[k] is obtained by -e[k]=PHF1[k]+PHF2[k], corresponding to -e[k]=(-e[k]+PHoffset). Then frequency synthesis is accomplished as the oscillator 10 tunes periods of the variable clock CKV to minimize (assuming type-II PLL) value of the signal PHF1[k], i.e., minimize (PHR[k]+PHV[k]+e[k])=(PHF1[k]+PHF2[k]).
In other words, the frequency synthesizer 30 can be analogous to an all-digital phase lock loop (ADPLL).

In an embodiment, the variable phase signal PHV[k], an integer, is a fixed point digital word of W1 bits. The reference phase signal PHR[k] is a fixed point digital word of (W1+WF) bits combining an integer part of W1 bits and a fractional part of WF bits. Each of the fractional error correction signals PHF1[k] and PHF2[k] is a fractional represented by a fixed point digital word of WF bits. The signal PHF[k] is a signed fixed point digital word of (WI+WF) bits including an integer part of W1 bits and a fractional part of WF bits.

Please refer to FIG. 5 illustrating an example of the phase shifter 46 according to an embodiment of the invention. In FIG. 5, the phase shifter 46 includes a divider 44 and a phase selector 48. The divider 44 is coupled to the oscillator 10, and arranged to divide the frequency of the variable clock CKV and to provide a plurality of clock candidates CKVp(1), CKVp(2), . . . , CKVp(n) to CKVp(Np) of different phases according to the variable clock CKV. For example, phase of the shifted clock candidate CKVp(n) is (n-1)360/Np degrees different from phase of the shifted clock candidate CKVp(1). The phase selector is coupled to the divider 44 and the shift controller 42, and arranged to select one of the shifted clock candidates CKVp(1) to CKVp(Np) as the shifted variable clock CKV in response to the shift control signal SEL of the shift controller 42.

In an embodiment, the divider 44 is arranged to divide the frequency of the variable clock CKV by two, and to accordingly provide four shifted clock candidates CKVp(1) to CKVp(4) of quadrature phases, with phases of the variable clock CKV and the shifted clock candidate CKVp(n) separated by a phase offset of 90° (n-1) degrees, for n=1 to 4. Please refer to FIG. 6 illustrating the TDC operation based on quadrature phases. With one of the four quadrature phases selected as the shifted variable clock CKV', the full range of the error -e[k] which expands 360 degrees (or one period Tv of the variable clock CKV) is mapped to a smaller range of the error -e[k], which extends only 90 degrees, or a quarter of the period Tv.

For example, when the error -e[k] is predicted to be in a range S0 of 0 to 90 degrees according to the fractional part PHR[k] of the reference phase signal PHR[k], the shift controller 42 selects the shifted clock candidate CKVp(1) as the shifted variable clock, so the error -e[k] is also in a range of 0 to 90 degrees; the shift controller 42 also injects a fractional error correction signal PHF2[k] equivalent of zero degrees to the adder 50. When the error -e[k] is predicted to be in a range S1 of 90 to 180 degrees, the shift controller 42 switches to select the shifted clock candidate CKVp(2) of a 90-degree phase offset as the shifted variable clock CKV', so the error -e[k] is kept in the range of 0 to 90 degrees. Correspondingly, the shift controller 42 also injects a fractional error correction signal PHF2[k] equivalent of 90 degrees (¼ in terms of the period Tv) to the adder 50.

Similarly, when the error -e[k] is expected to be in a range S2 of 180 to 270 degrees, the shifted clock candidate CKVp(3) of a 180-degree separation from the shifted clock candidate CKVp(1) is selected, the error -e[k] is then maintained in the range of 0 to 90 degrees; also, a fractional error correction signal PHF2[k] equivalent of 180 degrees is injected to the adder 50 (i.e., value of ½). When the error -e[k] is forecasted to be in a range S3 of 270 to 360 degrees, the shifted clock candidate CKVp(4) of a 270-degree separation from the shifted clock candidate CKVp(1) is selected, so the error -e[k] is still in the range of 0 to 90 degrees; to compensate the 270-degree phase offset subtracted from the error -e[k], a fractional error correction signal PHF2[k] equivalent of 270 degrees is injected to the adder 50.

As shown in FIG. 5, because the TDC 40 is arranged to detect the error -e[k] instead of the error -e[k], the TDC range of the TDC 40 only needs to cover a range of 0 to 90 degrees, or a quarter of the period Tv of the variable clock CKV, instead of full range of the period Tv.

For a brief summary of the embodiments shown in FIG. 3 to FIG. 6, peripherals for the TDC 40, including the phase shifter 46 and the shift controller 42, are provided. Based on the fractional part of the reference phase signal PHR[k], the regularly time-varying deterministic part of the error -e[k] can be predicted, so a corresponding phase offset PHFoffset can be dynamically set and subtracted from the error -e[k] to provide the error -e[k] which is kept in a range less than full range of the period Tv. The required TDC range of the TDC 40 is therefore decreased, and the TDC 40 benefits from lower hardware complexity (e.g., delay units and/or decoupling capacitors needed), reduced power consumption, smaller layout area, lower supply interference and enhanced linearity of time-to-digital conversion without compromising TDC temporal resolution. The shift controller 42 can be readily implemented by digital logic circuits.

Please refer to FIG. 7 illustrating a frequency synthesizer 60 according to an embodiment of the invention. Similar to the frequency synthesizer 30 shown in FIG. 3, the frequency synthesizer 60 in FIG. 7 has an FCW input 32a for receiving an FCW, a frequency reference input 32b for receiving a frequency reference clock FREFF, a reference frequency accumulator 34, a variable phase accumulator 36, a loop filter 38, an oscillator 10, a shift controller 62, a phase shifter 66, a TDC 40, an adder 50 and a re-timer 12. The oscillator 10 is arranged to provide a variable clock CKV, e.g., an RF clock, in response to an oscillator tuning word (OTW), such that the frequency of the variable clock CKV is an FCW multiple of the frequency reference clock FREFF when the variable clock CKV reaches a lock with the frequency reference clock FREFF. Operations and functionalities of the reference phase accumulator 34, the variable phase accumulator 36, the TDC 40, the adder 50 and the re-timer 12 in the frequency synthesizer 60 are analogous to those in the frequency synthesizer 30, FIG. 3. The variable phase accumulator 36 is coupled to the oscillator 10, and arranged to provide a variable phase signal PHV[k] by accumulating unit count at each significant transition of the variable clock CKV. The reference phase accumulator 34 is arranged to provide the reference phase signal PHR[k] by accumulating the FCW in response to significant transitions of an re-timed frequency reference clock CKR of the re-timer 12.

The phase shifter 66, e.g., a digital-to-time converter (DTC), is coupled to the frequency reference input 32b and the TDC 40, and arranged to provide a shifted reference clock FREFF by delaying (or changing phase of) the frequency reference clock FREFF in response to a shift control signal SEL. The variable clock CKV and the shifted reference clock FREFF are respectively fed to the TDC 40 as the signals TDC_in and REF_in, so the TDC 40 detects (quantizes) an error -e[k] (a time difference) between a significant transition of the shifted clock FREFF and a prior transition of the variable clock CKV, and provide a fractional error correction signal PHF1[k] in response. In cooperation with the phase shifter 66, the shift controller 62, e.g., a DTC compensator, is coupled to the phase shifter 66 and the adder 50, and arranged to provide the shift control signal SEL, and another fractional error correction shift PHF2[k] in response to the fractional part PHR[k] of the reference phase signal PHR[k]. With support of the shift controller 62
and the phase shifter 66, the TDC range of the TDC 40 is arranged to be less than a fraction of the period \( T_v \) of the variable clock \( CKV \).

Please refer to FIG. 8 illustrating cooperation of the phase shifter 66, the shift controller 62 and the TDC 40. While phase lock needs information about the error \( -e[k] \) between a significant transition of the frequency reference clock \( FREF \) and a prior significant transition of the variable clock \( CKV \), the shift controller 62 dynamically adjusts the shift control signal \( SEL \) and the fractional error correction signal \( PHF_1[k] \) according to the fractional part of the reference phase signal \( PHR[k] \), so the shift control signal \( SEL \) and the fractional error correction signal \( PHF_2[k] \) update following the deterministic part of the error \( -e[k] \). The phase shifter 66 is arranged to change phase (equivalently delay) of the frequency reference clock \( FREF \) by a phase offset \( PHD[k] \) which is set according to the shift control signal \( SEL \), wherein the phase offset \( PHD[k] \) is such arranged that the error \( -e[k] \) between a significant transition of the shifted reference clock \( FREF' \) and a subsequent significant transition of the variable clock \( CKV \) is less than a fraction of full range of the period \( T_v \) (also less than or equal to the error \( -e[k] \)). Equivalently, the phase offset \( PHD[k] \) is subtracted from the error \( -e[k] \) to form the error \( -e'[k] \). Because the TDC 40 only quantizes a shorter error \( -e'[k] \) instead of the error \( -e[k] \), TDC 40 benefits from a reduced TDC range. The fractional error correction signal \( PHF_2[k] \) is arranged to compensate the subtracted phase offset \( PHD[k] \), as shown in FIG. 7 and FIG. 8.

For example, when the error \( -e[k] \) is in a range of \( \frac{1}{4} \) to \( \frac{1}{2} \), the shift controller 62 sets the phase offset \( PHD[k] \) to preferably \( \frac{1}{2} T_v \), then the error \( -e'[k] \) to be measured by the TDC 40 is in a range of \( 0 \) to \( \frac{1}{4} \). When the error \( -e[k] \) is in a range of \( \frac{1}{4} \) to \( \frac{1}{2} \), the shift controller 62 switches to set the phase offset \( PHD[k] \) to preferably \( \frac{1}{2} T_v \) to \( \frac{1}{4} T_v \), so the error \( -e'[k] \) to be measured by the TDC 40 is maintained in the range of \( 0 \) to \( \frac{1}{4} \), rather than full range of \( 0 \) to \( 1 \). Because the TDC 40 is arranged to respond when a transition of the variable clock \( CKV \) and a transition of the shifted reference clock \( FREF' \) occur in a proximity of the TDC range, and not to respond when transitions of the variable clock \( CKV \) and transitions of the shifted reference clock \( FREF' \) do not occur in a proximity of the TDC range, hardware complexity (e.g., required delay units) of the TDC 40 is effectively reduced, leading to lower power consumption, less supply interference and enhanced linearity, etc.

In an embodiment, frequency of the frequency reference clock \( FREF \) is much lower than frequency of the RF variable clock \( CKV \), so the phase shifter 66 only needs to work at low-speed. In an embodiment, the phase shifter 66 is implemented by a DTOC which converts the digital shift control signal \( SEL \) (DTOC digital control) to the phase offset \( PHD[k] \) (a delay time interval). The DTOC can be implemented by a digitally programmable delay line. To ensure appropriate immunity against PVT (process, supply voltage and temperature) variation, proper mechanism and/or procedure for calibrating the DTOC can be included in the frequency synthesizer 60.

In the embodiment of FIG. 3, FIG. 5 and FIG. 7, the oscillator 10 works as a tuned oscillator; it is tuned so the variable clock \( CKV \) is tracking the frequency reference clock \( FREF \). The signal \( PHE[k] \) provided by the adder 50 feeds back to the oscillator 10 through the loop filter 38, and then the variable clock \( CKV \) can be further tuned in a finer sense. In an embodiment, the loop filter 38 is a digital low pass filter. The loop filter 38 can be constructed as a combination of FIR (finite impulse response) and IIR (infinite impulse response) filters. For example, in an embodiment, the loop filter 38 is arranged to provide the OTW by linearly combining the signal \( PHE \) and an accumulation of the signal \( PHE \), so the frequency synthesizer is a type II loop.

In the embodiment shown in FIG. 3, FIG. 5 and FIG. 7, the TDC 40 receives the high-speed shifted variable clock \( CKV \) (FIG. 3 and FIG. 5) or the variable clock \( CKV \) (FIG. 7) as the signal \( TDC_{in} \), and receives the low-speed frequency reference clock \( FREF \) (FIG. 3 and FIG. 5) or the shifted reference clock \( FREF' \) (FIG. 7) as the signal \( REF_{in} \). The TDC 40 quantizes the time difference between the signals \( TDC_{in} \) and \( REF_{in} \), and updates the fractional error correction signal \( PHF_1[k] \) at significant transitions of the signal \( REF_{in} \). However, the TDC 40 is kept receiving the high-speed toggling signal \( TDC_{in} \) so no matter the fractional error correction signal \( PHF_1[k] \) of the TDC 40 is triggered to update or not. High-speed toggling consumes large power, induces serious supply interference, and therefore degrades linearity of time-to-digital conversion. To address the issue, a power management circuit is arranged to suppress unnecessary pulses in the signal \( TDC_{in} \), only to keep a single pulse closest to a subsequent significant transition of the signal \( REF_{in} \), such that power consumption and supply interference are reduced without comprising normal time-to-digital conversion.

Please refer to FIG. 9 illustrating a frequency synthesizer 70 according to an embodiment of the invention. Similar to the frequency synthesizers 30 and 60, the frequency synthesizer 70 includes an FCW input \( 32a \) for receiving an FCW, a frequency reference input \( 32b \) for receiving a frequency reference clock \( FREF \), an oscillator 10 for generating a variable clock \( CKV \), a re-timer 12 for providing a re-timed reference clock \( CKR \) by re-timing the frequency reference clock \( FREF \) at significant transition of the variable clock \( CKV \), a reference phase accumulator 34 for providing a reference phase signal \( PHR[k] \) by accumulating the FCW in response to re-timed reference clock \( CKR \), a variable phase accumulator 36 for providing a variable phase signal \( PHV[k] \) by accumulating unit count at significant transitions of the variable clock \( CKV \), a TDC 80 for providing a fractional error correction signal \( PHF_1[k] \) by quantizing a time difference between the signals \( TDC_{in} \) and \( REF_{in} \), an adder 50 for providing the signal \( PHE[k] \), and a loop filter 38 for providing an OTW to the oscillator 10 in response to the signal \( PHE[k] \).

In addition, the frequency synthesizer 70 further includes a variable clock input \( 78a \) for receiving a signal \( TDC_{in0} \), another frequency reference input \( 78b \) for receiving a signal \( REF_{in0} \), a shift controller 72, a phase shifter 76 and a power management circuit 74. The shift controller 72 is arranged to provide another fractional error correction signal \( PHF_2[k] \) and the shift and control signal \( SEL \) in response to a fractional part \( PHR[k] \) of the reference phase signal \( PHR[k] \), so the adder 50 produces the signal \( PHE \) by adding an arithmetic difference \( (PHR[k]−PHV[k]) \) and an arithmetic sum \( (PHF_1[k]+PHF_2[k]) \). The phase shifter 76 is coupled to the shift controller 72, and arranged to change phase of the variable clock \( CKV \) or the frequency reference clock \( FREF \), and the signals \( TDC_{in0} \) and \( REF_{in0} \) are therefore provided according to the variable clock \( CKV \) and the frequency reference clock \( FREF \) respectively. The power management circuit 74 is coupled to the variable clock input \( 78a \) and the frequency reference input \( 78b \) for outputting the signals \( REF_{in} \) and \( TDC_{in} \), wherein the signal \( TDC_{in} \) is provided as a single pulse of the signal \( TDC_{in0} \) ahead of a subsequent significant transition of the signal \( REF_{in} \).
transits from logic to 1 in response to the shift control signal SEL, and accordingly provides the shifted variable clock CKV as the signal TDC_in0. The shift controller 72 injects the fractional error correction signal PHF2[k] to compensate the phase offset PHoffset, and the frequency reference clock FREF is provided to the power management circuit 74 as the signal REF_in0.

In another embodiment, cooperation of the shift controller 72 and the phase shifter 62 is similar to cooperation of the shift controller 62 and the phase shifter 66 (FIG. 7); the phase shifter 76 delays the frequency reference clock FREF by the phase offset PHdelay in response to the shift control signal SEL, and accordingly provides the shifted reference clock FREF as the signal REF_in0. The phase shifter 72 injects the fractional error correction signal PHF2[k] to compensate the phase offset PHdelay, and the variable clock CKV is provided to the power management circuit 74 as the signal TDC_in0.

Through cooperation of the shift controller 72 and the phase shifter 76, the time difference (the error e[k]) between the signals TDC_in0 and REF_in0 is kept in a range shorter than 8nB without compromising normal function of the TDC 80, hence they are not desirable.

Due to cooperation of the shift controller 72 and the phase shifter 76, duration of the error e[k] between the signals TDC_in0 and REF_in0 is in the TDC range shorter than the period TV, and the delay time TDelay can be set shorter than the period TV. On the contrary, if duration of the error e[k] is long, however, as the delay time TDelay is longer than the period TV, the window tends to capture more than one pulse in the signal TDC_in, and linearity of time-to-digital conversion could be, therefore, degraded, since more than one pulse before the significant transition 84b induces higher supply interference when the interval THA is measured.

By suppressing unnecessary pulses and maintaining a single pulse before a subsequent significant transition of the signal REF_in, high-speed toggling of the TDC 80 is avoided without compromising normal function of the TDC 80; thus power consumption is effectively reduced, and linearity of time-to-digital conversion is enhanced due to suppressed supply interference. The proper operation of the TDC 80 is not violated whether one (or more) pulse, such as the pulse 86d, appears in the signal TDC_in after the significant transition 84b of the signal REF_in, since the interval THA is measured (updated) before the significant transition 86d. The extra pulses, however, could negatively affect the power supply network operation, hence they are not desirable.

For a proper setting of the delay time TDelay, a lower bound of the delay time TDelay is the TDC range, an upper bound is set to avoid additional pulse(s) before the significant transition 84a. Accordingly, an accepted variation of the delay time TDelay is plus or minus (TV/2 - Tc)/2, where Tc denotes the TDC range.

Please refer to FIG. 11 and FIG. 12. FIG. 11 illustrates another power management circuit 7413 according to an embodiment of the invention, and FIG. 12 demonstrates operation of the power management circuit 7413 in two different cases. The power management circuit 7413 can be adopted to implement the power management circuit 74 shown in FIG. 9. The power management circuit 7413 includes two logic gates 82a and 82b, and a delay element 82c. The logic gate 82a is coupled to the signal REF_in0 and the REF_in at two inputs, and arranged to provide a gating signal CON in response to a logic operation result of the signals REF_in0 and REF_in, e.g., an AND of the signal REF_in0 and an inversion of the signal REF_in. The delay element 82c is coupled to the signal REF_in0 and the logic gate 82a, and arranged to provide the gating signal CON by delaying the reference signal REF_in0 with a delay time Tdelay. The logic gate 82b is coupled to the gating signal CON and the signal TDC_in0 at two inputs, and arranged to provide the signal TDC_in in response to an AND logic operation result of the signal TDC_in0 and the gating signal CON.

When the signal REF_in0 transits from logic 0 to logic 1 at a significant transition 84a, the logic gate 82a is arranged to set the gating signal to logic 1, and when the signal REF_in0 transits from logic 0 to logic 1 at a significant transition 84b, the logic gate 82a is arranged to set the gating signal CON back to logic 0. Hence, the gating signal CON maintains a window of logic 1 during the delay time TDelay between the significant transitions 84a and 84b. When the gating signal CON is of logic 0, the logic gate 82b is arranged to suppress pulses of the signal TDC_in0, and when the gating signal CON is of logic 1, the logic gate 82b is arranged to provide a single pulse 86a ahead of the subsequent significant transition 84b for the signal TDC_in by tracking the signal TDC_in0. In other words, as the signal TDC_in is provided according to the signal TDC_in0, only the single pulse 86a is reserved in the signal TDC_in, and other unnecessary pulses of the signal TDC_in0, such as pulses 86b and 86c, are suppressed by the gating signal CON. The signals REF_in and TDC_in are transmitted to the TDC 80, so the error e[k] is obtained as the TDC 80 detects (quantizes) a timing difference corresponding to an interval THA between a significant transition 84a of the pulse 86a and the subsequent significant transition of the signal REF_in.

By suppressing unnecessary pulses and maintaining a single pulse before a subsequent significant transition of the signal REF_in, high-speed toggling of the TDC 80 is avoided without compromising normal function of the TDC 80; thus power consumption is effectively reduced, and linearity of time-to-digital conversion is enhanced due to suppressed supply interference. The proper operation of the TDC 80 is not violated whether one (or more) pulse, such as the pulse 86d, appears in the signal TDC_in after the significant transition 84b of the signal REF_in, since the interval THA is measured (updated) before the significant transition 86d. The extra pulses, however, could negatively affect the power supply network operation, hence they are not desirable.
gating signal CON' back to logic 0 when the gating signal CON transits back to logic 0. In other words, during the window of the delay time Tdelay opened by the gating signal CON, the level sense circuit 82d opens a second window in the gating signal CON', when the signal TDC_in0 is of logic 0.

When the gating signal CON' is of logic 0, the logic gate 82b is arranged to suppress pulses of the signal TDC_in0, like the pulses 86a and 88b. When the gating signal CON' is of logic 1, the logic gate 82b is arranged to provide a single pulse 86a for the signal TDC_in by tracking the signal TDC_in0, such that only a single transition 84a of the pulse 86a exists ahead of the significant transition 84b of the signal REF_in. The TDC 80 detects the error $e_k$ by measuring an interval between the significant transitions 84a and 84b. In the signal TDC_in, because only the single pulse 86a presents before the significant transition 84b, unnecessary toggling of the TDC 80 is prevented, and linearity of the TDC 80 is enhanced.

As shown in case 2 of FIG. 12, if the gating signal CON is used to gate pulses of the signal TDC_in0, an additional pulse between the significant transition 90a and a falling edge 90d would be included in the signal TDC_in, and it could degrade linearity of the TDC 80. However, because the level sense circuit 82d adaptively avoids the duration when the signal TDC_in0 is of logic 1, the additional pulse is excluded by the narrower window of the gating signal CON; thus, existence of only a single pulse before the significant transition 84b is ensured for linearity preservation. By operation of the level sense circuit 82d, the power management circuit 74B is more robust with improved immunity against delay variation of the delay 82e, since tolerable delay variation of the delay time Tdelay is expanded to plus or minus $(T_v-T_c)/2$.

Please refer to FIG. 13 illustrating an example of the level sense circuit 82d, which includes an SR latch formed by two NAND gates 92a and 92b, as well as an inverter 94. The NAND gate 92a is respectively coupled to the signal TDC_in0, a node n0 and a node n1 at two inputs and an output. The NAND gate 92b is respectively coupled to the gating signal CON, the node n1 and the node n0 at two inputs and an output. The inverter 94 is coupled between the NAND gate 92b and the logic gate 82b. The gating signal CON’ is latched at logic 0 when the signal TDC_in0 is of logic 1, and released to follow the gating signal CON when the signal TDC_in0 is of logic 0.

To sum up, supporting peripherals for TDC in digital frequency synthesizers are provided. While monitoring the time difference (phase error) between the variable clock and the frequency reference clock by the TDC, phase of one of the variable clock and the frequency reference clock is adaptively shifted according to accumulation of the FCW, so the time difference is maintained in a partial range of the period of the variable clock, and TDC range can thus be set less than the period of the variable clock. In addition, unnecessary high-frequency toggling pulses to the TDC can be gated without compromising normal function of the TDC. Shorter TDC range and gated TDC toggling lead to advantages such as enhanced linearity of time-to-digital conversion, reduced hardware complexity, lower power consumption, smaller layout area, less required decoupling capacitance, and suppressed supply interference of the frequency synthesizer.

While the invention has been described in terms of what is presently considered to be the most practical and preferred embodiments, it is to be understood that the invention needs not be limited to the disclosed embodiment. On the contrary, it is intended to cover various modifications and similar arrangements included within the spirit and scope of the appended claims which are to be accorded with the broadest interpretation so as to encompass all such modifications and similar structures.

What is claimed is:

1. A frequency synthesizer comprising:
   a frequency reference input for receiving a frequency reference clock;
   a tuned oscillator for providing an RF clock;
   a phase shifter coupled to said frequency reference input and arranged to change phase of said frequency reference clock; and
   a time-to-digital converter (TDC) for producing a digital TDC output, said TDC coupled to said phase shifter and said tuned oscillator;

2. The frequency synthesizer of claim 1, wherein said phase shifter is a digital-to-time converter (DTC) for delaying said frequency reference clock in response to a DTC digital control.

3. The frequency synthesizer of claim 2, wherein said DTC digital control is set in response to an accumulated value of a frequency command word (FCW).

4. The frequency synthesizer of claim 2 further comprising:
   a shift controller coupled to said phase shifter for providing said DTC digital control in response to an accumulated value of a frequency command word (FCW).

5. The frequency synthesizer of claim 4, wherein said shift controller is further arranged to provide an auxiliary fractional error correction signal in response to said accumulated value of said FCW, and said tuned oscillator is further arranged to tune periods of said RF clock in response to said digital TDC output and said auxiliary fractional error correction signal.

6. The frequency synthesizer of claim 1 further comprising:
   a shift controller coupled to said phase shifter for providing an auxiliary fractional error correction signal in response to an accumulated value of a frequency command word (FCW);

7. The frequency synthesizer of claim 6, wherein said shift controller is further arranged to provide a DTC digital control in response to said accumulated value of said FCW, and said phase shifter is arranged to change phase of said frequency reference clock in response to said DTC digital control.

8. The frequency synthesizer of claim 1 further comprising:
   a variable phase accumulator coupled to said tuned oscillator for accumulating a count of periods of said RF clock and providing a variable phase signal in response; and
   a reference phase accumulator for providing an accumulated value of a frequency command word (FCW) by accumulating said FCW in response to each period of said frequency reference clock;

9. The frequency synthesizer of claim 8, wherein said phase shifter is arranged to change phase of said frequency reference clock in response to said accumulated value of said FCW, and said tuned oscillator is arranged to tune periods of said RF clock according to said digital TDC output, said variable phase signal and said accumulated value of said FCW.
9. The frequency synthesizer of claim 8 further comprising:
   a shift controller coupled to said phase shifter and arranged
to provide an auxiliary fractional error correction signal in
response to said accumulated value of said FCW;
wherein said tuned oscillator is arranged to tune periods of
said RF clock further according to said auxiliary frac­
tional error correction signal.

10. The frequency synthesizer of claim 1, wherein said phase shifter is arranged to change phase of said frequency reference clock and to provide a shifted reference clock accordingly, such that a time difference between a transition of said shifted reference clock and a previous transition of said RF clock is less than said full range of said RF clock period.

11. The frequency synthesizer of claim 1, wherein said phase shifter is arranged to provide a shifted reference clock by changing phase of said frequency reference clock, and said TDC is arranged to respond when a transition of said RF clock and a transition of said shifted reference clock occur in a proximity of said range, and not to respond when transitions of said RF clock and transitions of said shifted reference clock do not occur in a proximity of said range.

12. The frequency synthesizer of claim 1, wherein said phase shifter is arranged to shift said frequency reference clock in response to a fractional part of an accumulated value of a frequency command word (FCW).

13. A frequency synthesizer comprising:
   an oscillator for providing a variable clock;
a phase shifter arranged to provide a shifted reference clock
whose phase is arranged to be different from phase of a
frequency reference clock by a phase offset, wherein
said phase offset is such arranged that a time difference
between a transition of said shifted reference clock and
a prior transition of said variable clock is less than a
period of said variable clock; and
a time-to-digital converter (TDC) coupled to said phase shifter, and arranged to provide a first fractional error correction signal by quantizing said time difference; and
a variable phase accumulator coupled to said oscillator for
providing a variable phase signal by accumulating a
count of periods of said variable clock;
wherein said oscillator is further arranged to tune periods of said variable clock according to said variable phase signal.

14. The frequency synthesizer of claim 13 further comprising:
a reference phase accumulator for providing a reference phase signal by accumulating a frequency command word (FCW) in response to each period of said frequency reference clock;
wherein said phase shifter is arranged to set said phase offset in response to said reference phase signal.

15. The frequency synthesizer of claim 14 further comprising:
a shift controller coupled to said phase shifter, and arranged
to provide a second fractional error correction signal in
response to said reference phase signal;
wherein said oscillator is arranged to tune periods of said variable clock further according to said first fractional error correction signal and said second fractional error correction signal.

16. A frequency synthesizer comprising:
an oscillator for providing a variable clock;
a time-to-digital converter (TDC) arranged to provide a first fractional error correction signal by quantizing a time difference between a shifted reference clock and said variable clock, wherein phase of said shifted reference clock is arranged to be different from that of a frequency reference clock by a phase offset, and a range of said TDC covers less than a full range of said variable clock period; and
a shift controller arranged to provide a second fractional error correction signal in response to an accumulated value of a frequency command word (FCW); and
a variable phase accumulator coupled to said oscillator for
providing a variable phase signal by accumulating a
count of periods of said variable clock;
wherein said oscillator is further arranged to tune periods of said variable clock according to said first fractional error correction signal and said accumulated value of said FCW.

17. The frequency synthesizer of claim 16 further comprising:
a phase shifter coupled to said frequency reference clock, and
arranged to provide said shifted reference clock by changing phase of said frequency reference clock.

18. The frequency synthesizer of claim 16 further comprising:
a reference phase accumulator arranged to provide said accumulated value of said FCW by accumulating said FCW in response to each period of said frequency reference clock.

19. A method of synthesizing a frequency by providing an
associated variable clock, comprising:
generating said variable clock in response to an oscillator tuning signal;
phase shifting a frequency reference clock by a phase offset to obtain a shifted reference clock;
digitizing a timing difference of said variable clock and said shifted reference clock such that range of said digitizing covers less than a full range of said variable clock period.

20. The method of claim 19 further comprising:
adjusting said phase offset such that a time difference between a transition of said shifted reference clock and a prior transition of said variable clock is less than or equal to a time difference between a transition of said frequency reference clock and a prior transition of said variable clock.

21. The method of claim 20 further comprising:
obtaining an accumulated value of a frequency command word (FCW) by accumulating said FCW according to periods of said frequency reference clock; and
adjusting said phase offset in response to a fractional part of said accumulated value of said FCW.

22. The method of claim 21 further comprising:
obtaining a first fractional error correction signal in
response to said digitizing; and
adjusting said oscillator tuning signal in response to said first fractional error correction signal.

23. The method of claim 22 further comprising:
obtaining a second fractional error correction signal in
response to said phase offset;
adjusting said oscillator tuning signal further in response to
said second fractional error correction signal.
